

Automation triggers

Triggers define **when** a rule should be executed - so **every rule starts with a trigger**.

A trigger must be the first element when configuring a rule and can only occur **once per rule**. Triggers will generally listen to events. Typical events are **field**, **issue**, **project**, or **system** events (e.g. "A field was updated", "A new version was created").

Apart from **events**, a trigger can be:

- **scheduled** to only be executed at certain times or
- ran **manually**

Available automation triggers

The following **triggers** are available:

Field changed event

Issue event

Issue transitioned event

Project event

System event

Scheduled trigger

Manual trigger

A trigger **must** be the **first element** in the rule configuration and can only occur **once per rule**.

For the rule to execute, the **conditions** configured for a chosen trigger must be met.
