

Numeric mode

The **numeric** parsing mode is the perfect fit if you need to perform any kind of calculation or if you want to simply set a **numeric** field, such as Story Points.

This mode accepts the use of **field codes** which will be replaced at **runtime** with the corresponding field value of the issue currently being processed.

Field codes need to either return a number or a **timestamp**. Alternatively they can be converted (cast) from a text to number (e.g. using [toNumber\(\)](#)). Additional information can be found in the [Data types](#) section.

123 Example expressions

Parser expression	Description
<code>1 + 1</code>	This example returns: 2.0
<code>round(0.75)</code>	This example returns: 1.0
<code>addDays({issue.duedate}, 2, LOCAL)</code>	This example adds 2 days to the issue's due date. The numeric mode can also be used for all date and date-time calculations. Do you want to see the result as a string? Just switch to the Advanced text mode and wrap your expression around one of the following functions: • monthToString() • dateToString() • dateTimeToString() • formatDuration() • formatWorkDuration()

Make sure to read all about working with [Numbers](#) and [Dates, times and time zones](#) as they come with many extremely useful [JWT expression parser functions](#).
